This note compares the new Hybrid approach to aviation emissions with the Trading options using the original criteria as considered by IACO in 2004 (CAEP-SG20041-WP/3).

| ummary of S | ystem Design | Elements for: | Trading (ICA | AO, 2004) & | Hybrid "Charge & Cap |
|--|--|--|--|--|---|
| Design Element | Option 1. Aviation Emissions Trading System with ICAO Guidance | Option 2A. ICAO Cap System for Airlines | Option 2B. ICAO Binding Dual Target System for Airlines | Option 3. ICAO Assisted Voluntary Emissions Trading System | Option 2007: "Charge & Cap" emission fund climate change actio |
| Basis for trading regime | Kyoto Protocol or successor agreement comes into force, w/ analogue to AAUs. | New stand-alone treaty or agreement created under ICAO auspices | | Voluntary trading rules agreed to by participating entities | Kyoto Protocol and any project-based agreements (like CDM). |
| Form of emission instrument | AAUs or equivalent are created for international bunker fuels | Instrume | nts are created under ne | w regimes | None created; Aviation is a net buyer of emission certificates. |
| Aggregate environmental target | All international aviation emissions represented by AAUs | Commitments covering emissions along specified routes with origins and destinations in participating countries. Environmental benefits depend on targets agreed to and degree of participation | | Environmental benefits depend on targets agreed to and degree of participation | Global emissions capped on an agreed level. |
| Overall structure: cap vs. credit | Cap (if countries have domestic trading systems and include aviation) | Allowance cap negotiated within ICAO | Binding upper target and non-binding lower target negotiated within ICAO | Binding cap agreed to voluntarily by participants | Charge to deliver binding emission cap and provide funding for adaptation and future mitigation. |
| Participants in the system (entities that must report and be in compliance) | Airlines licensed in countries that ratify Kyoto or successor climate agreement | Airlines based in those countries that sign agreement/treaty committing them to participate in the ICAO trading regime | | Airlines that agree to participate in system) | All international flight operators for charges; the Fund for trading & global cap. |
| Role of ICAO | ICAO provides guidance on trade in aviation emission instruments, including domestic aviation | ICAO or designated Secretariat, creates allowances for international aviation and designs and administers trading system | ICAO, or designated Secretariat, designs and administers trading system and certifies the generation of credits | ICAO assists with design, facilitation, and information support. | Oversee the Fund, review and adjust the sub-funds structure (every 3 years). |
| Role of country governments | Parties to Kyoto Protocol receive AAUs and control domestic and international aviation via emissions trading or other system | ICAO member states sign onto agreement establishing authority for trading system, and carry out enforcement for airlines licensed in their countries | | Little role, since the nature of the commitment means that agreement is enforced among participating entities | ICAO member states sign onto agreement allowing the collection of charges the supranational Fund (through ATCs). |
| Openness and interaction with international instrument | Complete buying and selling with international system | Participants can use international instruments (or internal trades) for compliance For ICAO system allowances or credits to be sold outside system requires acceptance by outside entities. | | Subject to the rules of other trading regimes, can purchase from but not sell into other regimes | Complete buying and selling of certificates except of national allocat units (selling of only previously acquired asse – none issued). |
| Basis for identifying participating entity (airline) commitments | Depends on system and whether (and how) airlines are included | Negotiated commitments covering emissions on specified routes | Negotiated dynamic binding targets covering emissions on specified routes | Absolute or relative baseline is basis for credit generation | No individual caps – impa internalized completely through emission charge |
| Allowance distribution mechanism | Free distribution of allowances | Free distribution of allowances | n/a | Agreed to by participants | No allowances. |

| Evalu | ation Criteria | Option 1. Aviation Emissions Trading System with ICAO Guidance | Option 2A. ICAO Cap System for Airlines | Option 2B. ICAO Binding Dual Target System for Airlines | Option 3. ICAO Assisted Voluntary Emissions Trading System | Option 2007: "Charge & Cap" emission, Fund climate change action |
|--|---|---|---|--|--|---|
| Environmental Results | Stringency of environmental target | Determined by the AAUs created for international aviation | Determined by stringency of overall cap and whether grows over time | Depends on aggregated stringency of upper targets for airlines | Depends on nature of voluntary commitments, but likely to be small | Determined by the cap (proposed to cap emission on the 2005 level till 2050 |
| | Certainty with which environmental goals are met | Because AAUs provide a cap, achieve overall environmental results with certainty | Overall cap is achieved with certainty throughout system | Because upper target is binding, achieves that goal with certainty | Because participation is voluntary, environmental achievements are uncertain | Certainty through market approach, early action & banking; overachievemen as a stretch target. |
| Economic Growth and Contraction | Allows for growth in international aviation | Growth could be accommodated in the algorithm for distributing allowances to individual airlines as designated by countries, and in airlines' ability to buy allowances to meet commitments | Growth depends on overall cap and on how allowances are distributed to individual airlines Can build growth into hard cap by adjusting over time or revisiting periodically, but can be difficult Can compensate for growth by buying allowances | Growth depends on how upper targets are determined for individual airlines If use dynamic target, can build growth into target directly for individual airlines Can compensate for growth by buying allowances | Growth depends on how targets are determined for individual airlines If use dynamic target, can build growth into target directly for individual airlines Can compensate for growth by buying allowances | Growth accommodated a each airline pays for actu emissions. Reductions achieved through the most cost- effective approach globa |
| Economic | Has potential for erosion of environmental benefits ("hot air") | Environmental benefits can be reduced if sector faces dramatic economic downturn not built into cap | Environmental benefits can be reduced if sector faces dramatic economic downturn not built into cap | Less potential for benefits to be eroded, if lower target is stringent and depends on output or other variables | Less potential for benefits to be eroded, since excess emissions cannot be sold outside sector; may be affected by rules governing acceptable trades | Cap set low for a very lon period – "hot air" very unlikely. Benefits also achieved in the funding areas: future mitigation & adaptation |
| Breadth of emissions coverage: geographic coverage of airlines and routes | | Narrow—only international aviation emissions allocated to Parties to the Kyoto Protocol or successor protocol | International emission operated by airlines in ICAO member States in system—potentially | chooses to participate | International emissions by airlines choosing to participate in agreement—potentially global | Global; 99% of international flight |
| Administrative and Transactions Costs | Cost of administering the system for central authorities | Low because of allowances and supporting institutions and infrastructure will exist | Moderate because supporting institutions and infrastructure will have to be created | Moderate to high because of new institutions and infrastructure, the dual target s, and certification | Depends on structure but likely to be low moderate because of lower compliance and enforcement | Low: Collection through existing ATCs; disbursement centralized through three sub-funds. |
| | Transaction costs for participants | Moderate because of potential complications with domestic systems | Low because of allowances | Moderate because dual target requires dual accounting and some certification | Depends on structure but likely to be low to moderate | Very low; no allowances issued, no additional compliance costs. |
| | Complexity of ICAO role | Low—role is one of analysis and providing guidance and information | High—System design, administration and overseeing allowances & trading | High—System design, administration and baseline determination | Low—role in assisting with design and possibly providing administrative support and information | Low: emission guidance; review & fund adjustment every 3 y (this role might be performed by UNFCC0 |

| C | Comparison and Evaluation of System Design (#2): Trading (2004) & Hybrid "Charge & Cap" | | | | | | | |
|----------------------------|---|--|---|---|---|---|--|--|
| Evalu | ation Criteria | Option 1. Aviation Emissions Trading System with ICAO Guidance | Option 2A. ICAO Cap System for Airlines | Option 2B. ICAO Binding Dual Target System for Airlines | Option 3. ICAO Assisted Voluntary Emissions Trading System | Option 2007: "Charge & Cap" emission, Fund climate change action | | |
| issue airline aviati | betitiveness s across es and between on and other portation | Competitiveness issues between airlines in nations that do and do not participate Fewer issues between international aviation and domestic aviation or other transportation modes | Competitiveness issues along routes between airlines in nations that do and do not participate Broader coverage decreases the potential for competitiveness issues | Competitiveness issues along routes between airlines in nations that do and do not participate Broader coverage decreases the potential for competitiveness issues | Provided it attracts greater participation, competitiveness concerns would be less than for other systems | None for international aviation (assumes that all airlines participate in this region agnostic solution). | | |
| Policy Context | Legal/policy constraints | No new instrument Requires distribution of AAUs for international aviation | Requires international agreement among ICAO members If system is to be fully open, requires a new instrument that is accepted outside the system | Requires international agreement among ICAO members If system is to be fully open, requires a new instrument that is accepted outside the system | Requires agreement of entities | Requires global aviation agreement only (scheme designed to make it acceptable to airlines, developed and developing countries). | | |
| | Interactions with other emissions trading systems | Must be consistent with rules being developed for international emissions trading under Kyoto Protocol or successor protocol and with individual systems | Must be consistent with rules being developed for other emissions trading systems so that system can be open | Must be consistent with rules being developed for other emissions trading systems so that system can be open | Allows the purchase of reductions from other sectors Aviation reductions would not be transferable outside of the aviation sector | Works with any trading platform through the UNFCCC ITL registry. Allows the trading of emission certificates (CDM etc.). | | |
